Joint Channel and Carrier Estimation Using Extended Kalman Filter

Grzegorz Haza

Abstract—In this paper a proposal of joint channel and carrier estimation using extended Kalman filter (EKF) is presented. For the proposed algorithm simulations are performed and the results are compared with the separate channel estimation based on the Kalman filter (KF) and carrier estimation based on the extended Kalman filter (EKF).

Keywords—extended Kalman filter, EKF, joint channel and carrier estimation, synchronization, digital receiver.

I. INTRODUCTION

Estimation and synchronization of communication signal parameters is an important task in a design of coherent receivers that consume significant attention of engineers. A common approach for estimation of an impulse response of a communication channel and a residual carrier frequency offset is based on a disjoint adaptive Least Mean Squares (LMS) channel estimation [1]–[4] with frequency synchronization based on a phase locked loop (PLL) [1], [2], [5], [6] with an appropriate phase error detector (PED) [1], [2], [5], [6].

However, this technique suffers from the fact, that both algorithms are based on a fixed adaptation parameters which, in case of the LMS channel estimation is represented by an adaptation step [1], [3], [4] and for the PLL carrier synchronization, by a loop filter parameters related with the loop bandwidth [1], [2], [5], [6]. As a result of fixed step–size adaptation procedure, the algorithms must be preconfigured in order to provide quick adaptation or small value of estimation error in the steady state. These both contradictions can not be met for its best performance at the same time. Since the adaptation steps do not depend on the actual conditions of the received signal, it is often a compromise between a maximum acceptable time of adaptation and a desired steady state error estimation.

Because of this, more advanced adaptive techniques for the channel estimation, for instance based on the RLS algorithm [1], [3], [4] or the Kalman filter [1], [3], [4] and for the phase estimation and synchronization, techniques based on a variable step PLL [7], on the Kalman filter with an appropriate phase detector [8] or on the extended Kalman filter [9] were proposed.

In this paper, a joint channel and carrier estimation based on the extended Kalman filter (EKF) is proposed. This technique relies on the concept of applying the EKF for a carrier frequency estimation presented in [9]. However, we use a state-space nonlinear dynamical model that incorporates both, the carrier frequency and the finite impulse response (FIR) type channel parameters at once in an iterative estimation procedure.

The paper is organized as follows. At the beginning, the state-space model description for complex signals and then a representation with separated real and imaginary parts is provided. Next, the application of the Extended Kalman Filter for described state-space model is proposed and later on, simulation results are shown and described. Finally, some conclusions are given at the end of this paper.

II. MODEL DESCRIPTION

A. State-space Model a Nonlinear Dynamical System

Assume, that the input signal $y(t)$ at the receiver is at first downconverted to the baseband representation with the residual carrier frequency offset (CFO), then matched filtered and sampled with perfect timing information with time step $T_s = 1/f_s$ for one sample per symbol, so the following discrete time complex representation can be applied [1], [5]:

$$y_n = \sum_{k=0}^{L-1} h_k b_{n-k} \exp \{j\omega_0 n T_s\} + v_n$$

where $h = [h_0, \ldots, h_k, \ldots, h_{L-1}]^T$ is the finite impulse response channel type of length $L$ introducing inter–symbol interference, which is assumed to be complex valued so, that $h_k \in \mathbb{C}$ for $k = 0, \ldots, L - 1$. Transmitted symbol $b_n \in \mathbb{Z}$ is assumed to be independent and identically distributed random variable (iid RV) with uniformly distributed symbols taken from m–PSK or m–QAM constellation [1], [2], [5], [6]. The exponential component $\exp \{j\omega_0 n T_s\}$ is responsible for the multiplicative distortion [1] with a frequency offset value $\omega_0 \in \mathbb{R}$ and time–variable phase $\phi_n = \omega_0 n T_s \in \mathbb{R}$, which can be caused i.e., by an imperfect carrier frequency of generators at the sending and receiving end, a Doppler frequency offset or both [1], [2], [5], [6]. The additive noise term $v_n$ is assumed to be complex valued, zero-mean, white Gaussian noise (Additive White Gaussian Noise – AWGN).

Our goal is to perform an iterative and joint estimation of the carrier phase $\phi_n \in \mathbb{R}$, the carrier frequency offset $\omega_n \in \mathbb{R}$ and the channel impulse response $h_n$ of length $L$ where $h_n[k] \in \mathbb{C}$ for $k = 0, \ldots, L - 1$, using the Extended Kalman filter, which operates in the state–space model of a nonlinear dynamical system.

In order to achieve this goal, we assume at first a process equation of the dynamical system described as below

$$x_n = Ax_{n-1} + w_n$$

where the process equation at time instant $n$ and $n-1$ contains consecutively $x_n = [\phi_n, \omega_n, h_n]^T$ and
The process equation is of size $L + 2 \times L + 2$ and it is described as follows

$$A = \begin{bmatrix}
1 & T_s & 0_{1 \times L} \\
0 & 1 & 0_{1 \times L} \\
0_{L \times 1} & 0_{L \times 1} & A_h
\end{bmatrix} \tag{3}$$

where the channel propagation matrix is defined as $A_h = I_{L \times L}$. A process noise $w_n = [w_{\phi,n}, w_{\omega,n}, w_{h,n}^T]^T$ is a vector of size $L \times 1$, where $w_{\phi,n} \in \mathbb{R}$ and $w_{\omega,n} \in \mathbb{R}$ but, on the other hand, an additive channel model noise is assumed to be $w_{h,n}[k] \in \mathbb{Z}$ for $k = 0, \ldots, L - 1$. The process noise $w_n$ is assumed to be additive, zero mean, white and Gaussian [4], [10]. With the aforementioned representation, both the carrier frequency offset and the channel characteristic are included in the vector representation of the process equation of the dynamical system.

For the EKF purposes, assuming the AWGN measurement noise $v_n$, a general measurement equation of the nonlinear state–space dynamical model, which is related to the process equation $x_n$ and the vector $b_n = [b_0, b_{n-1}, \ldots, b_{n-L+1}]^T$ of size $L \times 1$ with transmitted symbols, can be described by the following formula [10]

$$y_n = c[x_n, b_n] + v_n \tag{4}$$

Between the process and measurement equations a nonlinearity represented by the multiplicative distortion [1], that includes the phase $\phi_n$ of the process equation $x_n$ is present. This nonlinearity can be placed into the aforementioned formula by the following relation

$$c[x_n, b_n] = h_n^T b_n \exp \{j \phi_n\} \tag{5}$$

In order to enable state estimation for the nonlinear measurement equation using the Extended Kalman Filter, it is necessary to perform linearisation by expanding the nonlinearity into the first order Taylor series [4], [10] at the reference point $x_{n, ref}$ according to the following approximation

$$c[x_n, b_n] \approx c[x_{n, ref}, b_n] + \frac{dc[x_{n, ref}, b_n]}{dx_{n, ref}} \delta x_n \tag{6}$$

where $\delta x_{n, ref}$ is the state perturbation, which can be represented by

$$\delta x_{n, ref} = x_n - x_{n, ref} \tag{7}$$

and the first derivative (6) is the Jacobian of size $1 \times L + 2$, which can be restated as

$$C[x_{n, ref}, b_n] = \begin{bmatrix}
C_{\phi}[x_n, b_n] \\
C_{\omega}[x_n, b_n] \\
C_h[x_n, b_n]
\end{bmatrix} \bigg|_{x_n = x_{n, ref}} \tag{8}$$

For convenience, the above Jacobian is partitioned into partial derivatives of the carrier phase $\phi_n$, the carrier frequency offset $\omega_n$ and the channel impulse response $h_n$, so the following matrix representation of size $1 \times L + 2$ is obtained

$$C[x_n, b_n] = \begin{bmatrix}
C_{\phi}[x_n, b_n] \\
C_{\omega}[x_n, b_n] \\
C_h[x_n, b_n]
\end{bmatrix}^T \tag{9}$$

The derivative of the nonlinearity $c[x_n, b_n]$ according to the phase $\phi_n$ results in a scalar value described by

$$C_{\phi}[x_n, b_n] = \frac{dc[x_n, b_n]}{d\phi_n} = h_n^T b_n \exp \{j \phi_n\} \tag{10}$$

At the same moment, the derivative according to the carrier frequency offset $\omega_n$ results as follows

$$C_{\omega}[x_n, b_n] = \frac{dc[x_n, b_n]}{d\omega_n} = 0 \tag{11}$$

And finally, the partial derivative according to the channel vector $h_n$ returns a following vector of size $1 \times L$

$$C_h[x_n, b_n] = \frac{dc[x_n, b_n]}{dh_n} = b_n^T \exp \{j \phi_n\} \tag{12}$$

B. Separating Real and Imaginary Components

We want to note, that the process equation of the dynamical system consists of two real valued parameters: $\phi_n$ and $\omega_n$, which are related to the residual carrier frequency offset of the measurement equation and the complex valued channel impulse response $h_n$. All these parameters in the process equation distort the transmitted symbols $\{b_n\}$, which are present in the measurement equation $y_n$ by the transformation $c[x_n, b_n]$. Since both, real and complex valued variables are available at the same process equation of the dynamical system, its estimation conducted on the aforementioned measures $y_n$ can lead to the complex valued estimates of both $\phi_n$ and $\omega_n$ carrier parameters. In this case, the time–variant phase offset becomes $\phi_n = \phi_{R,n} + j \phi_{I,n}$ with possibly non-zero imaginary part, which can strictly result in an unwanted additional exponential amplitude distortion of the measurement equation $y_n$, according to the following relation

$$y_n = c[x_n, b_n] + v_n = h_n^T b_n \exp^{j \phi_{R,n}} \exp^{j \phi_{I,n}} + v_n \tag{13}$$

where $e^{j \phi_{R,n}}$ represents the unwanted additional nonlinear relation between the amplitude of the measurement and the imaginary part of the parameter $\phi_n$ from the process equation. Since we want to avoid this situation, we adopt the approach for the carrier estimation based on the EKF presented in paper [9] for the joint channel and carrier estimation.

At first, we rewrite the process equation $x_n$ using its new representation $x_n^{IQ}$, which contains separated real and imaginary parts of the channel impulse response $h_n$ according to the following vector of size $2L + 2 \times 1$ representation

$$x_n^{IQ} = \begin{bmatrix}
\phi_n \\
\omega_n \\
\Re \{h_n^{IQ}\} \\
\Im \{h_n^{IQ}\}
\end{bmatrix} \tag{14}$$

where $h_n^{IQ} = [\Re \{h_n^{IQ}\}, \Im \{h_n^{IQ}\}]^T$ is a vector of size $2L \times 1$. Then, we introduce a new representation of the nonlinearity $c[x_n, b_n]$, which is now a vector of size $2 \times 1$ described by the relation

$$c^{IQ}[x_n^{IQ}, b_n^{IQ}] = \begin{bmatrix}
\Re \{c[x_n, b_n]\} \\
\Im \{c[x_n, b_n]\}
\end{bmatrix} \tag{15}$$
This enabled us to establish a new vector representation of the measurement equation of size $2 \times 1$

$$y_n^{IQ} = c^{IQ}[x_n^{IQ}, b_n^{IQ}] + v_n^{IQ}$$  \hspace{1cm} (16)

where $y_n^{IQ}$ is related with $y_n$ according to $y_n^{IQ} = \begin{bmatrix} \Re \{y_n\} \\ \Im \{y_n\} \end{bmatrix}$ and an additive measurement noise $v_n^{IQ}$, which is related to the measurement noise $v_n$ according to $v_n^{IQ} = \begin{bmatrix} \Re \{v_n\} \\ \Im \{v_n\} \end{bmatrix}$.

For the new representation of the state and measurement components, we can introduce now a new Jacobian matrix $C_{x_n,ref}^{[IQ],IQ}$ of size $2 \times 2L + 2$ by recalculating partial derivatives of the nonlinearity $c^{IQ}[x_n^{IQ}, b_n^{IQ}]$ at the reference point $x_{n,ref}^{IQ}$ according to the following relation

$$C_{x_n,ref}^{[IQ],IQ} = \left[ \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{dx_n^{IQ}} \right] \left|_{x_n^{IQ}=x_{n,ref}^{IQ}} \right.$$ \hspace{1cm} (17)

As before, we are partitioning the calculation of the derivatives in order to obtain partial results $C_\phi^{[IQ],IQ}$ for the phase $\phi_n$, $C_{b}^{[IQ],IQ}$ for the carrier frequency offset $\omega_n$, and $C_{h}^{[IQ],IQ}$ for the channel impulse response $h_n^{IQ}$ and we are relating the results with its complex counterparts obtained in the previous section.

First, we calculate the derivative of $c^{IQ}[x_n^{IQ}, b_n^{IQ}]$ according to the phase $\phi_n$ which results as a vector of size $2 \times 1$ represented by

$$C_\phi^{[IQ],IQ} = \left[ \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\phi_n} \right] = \left[ \begin{array}{c} \Re \{C_\phi[x_n, b_n]\} \\ \Im \{C_\phi[x_n, b_n]\} \end{array} \right]$$ \hspace{1cm} (18)

It can be further calculated for the real and imaginary components of the above partial derivative consecutively as

$$\frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\phi_n} = \begin{bmatrix} -\sin(\phi_n)\left( h_{R,n}^{T} b_{3,n} - h_{T,n}^{T} b_{3,n} \right) \\ -\cos(\phi_n)\left( h_{R,n}^{T} b_{3,n} + h_{T,n}^{T} b_{3,n} \right) \end{bmatrix} = \Re \{C_\phi[x_n, b_n]\}$$ \hspace{1cm} (19)

and

$$\frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\phi_n} = \begin{bmatrix} \cos(\phi_n)\left( h_{R,n}^{T} b_{3,n} - h_{T,n}^{T} b_{3,n} \right) \\ \sin(\phi_n)\left( h_{R,n}^{T} b_{3,n} + h_{T,n}^{T} b_{3,n} \right) \end{bmatrix} = \Im \{C_\phi[x_n, b_n]\}$$ \hspace{1cm} (20)

Thus, the derivative $C_\phi^{[IQ],IQ}$ is related with the derivative $C_{\phi}^{[IQ]}$ in the following manner

$$C_\phi^{[IQ],IQ} = \left[ \begin{array}{c} \Re \{C_\phi[x_n, b_n]\} \\ \Im \{C_\phi[x_n, b_n]\} \end{array} \right]$$ \hspace{1cm} (21)

To obtain the derivative of $c^{IQ}[x_n^{IQ}, b_n^{IQ}]$ according to the carrier frequency offset $\omega_n$, represented by the vector $C_{\omega}^{[IQ],IQ}$ of size $2 \times 1$, we introduce the following relation

$$C_{\omega}^{[IQ],IQ} = \left[ \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\omega_n} \right] = \begin{bmatrix} \Re \{C_{\omega}[x_n, b_n]\} \\ \Im \{C_{\omega}[x_n, b_n]\} \end{bmatrix}$$ \hspace{1cm} (22)

Finally, in order to calculate the partial derivative of the nonlinearity $c^{IQ}[x_n^{IQ}, b_n^{IQ}]$ according to the new channel impulse response vector $h_n^{IQ}$ we introduce and then partition the matrix $C_h^{[IQ],IQ}$ of size $2 \times 2L$ according to

$$C_h^{[IQ],IQ} = \left[ \begin{array}{c} \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{dh_n^{IQ}} \\ \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\omega_n} \end{array} \right] = \left[ \begin{array}{cc} \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{dh_n^{IQ}} & \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\omega_n} \\ \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{dh_n^{IQ}} & \frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\omega_n} \end{array} \right]$$ \hspace{1cm} (23)

Each component from the partitioned matrix $C_h^{[IQ],IQ}$ is calculated as follows

$$\frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{dh_n^{IQ}} = \begin{bmatrix} b_{3,n}^T \cos \phi_n - b_{3,n}^T \sin \phi_n \\ -b_{3,n}^T \cos \phi_n + b_{3,n}^T \sin \phi_n \end{bmatrix} = \left[ \begin{array}{c} \Re \{C_h[x_n, b_n]\} \\ \Im \{C_h[x_n, b_n]\} \end{array} \right]$$ \hspace{1cm} (24)

$$\frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\omega_n} = \begin{bmatrix} -b_{3,n}^T \cos \phi_n + b_{3,n}^T \sin \phi_n \\ \Re \{C_h[x_n, b_n]\} \end{array} \right]$$ \hspace{1cm} (25)

$$\frac{dc^{IQ}[x_n^{IQ}, b_n^{IQ}]}{d\omega_n} = \begin{bmatrix} -b_{3,n}^T \cos \phi_n + b_{3,n}^T \sin \phi_n \\ \Im \{C_h[x_n, b_n]\} \end{array} \right]$$ \hspace{1cm} (26)

Applying the above results (24)–(27) into (23), we can restate the matrix $C_h^{[IQ],IQ}$ using its complex counterparts from the previous section $C_{\phi}^{[IQ]}$, $C_{\omega}^{[IQ]}$, and $C_{\omega}^{[IQ]}$ as

$$C_h^{[IQ],IQ} = \left[ \begin{array}{c} \Re \{C_h[x_n, b_n]\} \\ \Im \{C_h[x_n, b_n]\} \end{array} \right] = \left[ \begin{array}{c} \Re \{C_{\phi}^{[IQ]}[x_n, b_n]\} \\ \Im \{C_{\phi}^{[IQ]}[x_n, b_n]\} \end{array} \right]$$ \hspace{1cm} (28)

Reassembling, the partial derivative of the nonlinearity which is represented as the matrix of size $2 \times 2L + 2$

$$C_{\phi}^{[IQ]} = \left[ \begin{array}{c} \Re \{C_{\phi}^{[IQ]}[x_n^{IQ}, b_n^{IQ}]\} \\ \Im \{C_{\phi}^{[IQ]}[x_n^{IQ}, b_n^{IQ}]\} \end{array} \right]$$ \hspace{1cm} (29)

can be further restated as follows

$$C_{\phi}^{[IQ]} = \left[ \begin{array}{c} \Re \{C_{\phi}^{[IQ]}[x_n^{IQ}, b_n^{IQ}]\} \\ \Im \{C_{\phi}^{[IQ]}[x_n^{IQ}, b_n^{IQ}]\} \end{array} \right]$$ \hspace{1cm} (30)

### III. Algorithm Description

The extended Kalman filter is a well known method in iterative estimation of a state vector in a nonlinear model of a dynamical system [4], [10]. On the contrary to the Kalman filtering, which is designed for the linear models, the EKF can handle nonlinearities thanks to the linearisation procedure [4], [10], thus it provides an approximation to the optimal nonlinear estimation [4], [10]. In this section, the application of the EKF for the joint channel and carrier estimation is provided.

Prediction of the process equation of the dynamics at time $n$ is described by the vector of size $2L + 2 \times 1$

$$x_{n|n-1} = A^{IQ} x_{n-1|n-1}$$ \hspace{1cm} (31)
where the transition matrix $A^{IQ}$ of size $2L + 2 \times 2L + 2$ is related with the transition matrix $A$ of size $L + 2 \times L + 2$ by the following relation:

$$A^{IQ} = \begin{bmatrix} A & 0_{L+2\times L} \\ 0_{L \times L+2} & A_h \end{bmatrix}$$

(32)

where the channel model is assumed $A_h = I_{L \times L}$.

The error of the a priori estimate of the process equation $x_{n|n-1}$ according to the true state $\hat{x}_{n}^{IQ}$ is defined by

$$e_{n|n-1}^{IQ} = x_{n}^{IQ} - x_{n|n-1}^{IQ}$$

(33)

In the Extended Kalman Filter it is assumed [4], [10], that the reference point is equal to the a priori estimate of the process equation

$$x_{n,ref} = x_{n|n-1}$$

(34)

From (15), the nonlinear relation $c^{IQ}[x_{n|n-1}^{IQ}, b_{n}^{IQ}]$ between the a priori estimate of the process equation and the a priori estimate of the measurement $y_{n|n-1}^{IQ}$ can be defined by the vector of size $2 \times 1$ of the form

$$c^{IQ}[x_{n|n-1}^{IQ}, b_{n}^{IQ}] = \begin{bmatrix} 3 \{ c[x_{n|n-1}, b_n] \} \\ \{ c[x_{n|n-1}, b_n] \} \end{bmatrix}$$

(35)

where $c[x_{n|n-1}, b_n] = h_n^T x_{n|n-1} + b_n \exp \{ j \phi_n \}$. Thus, the a priori measurement equation is defined as follows

$$y_{n|n-1}^{IQ} = c^{IQ} \begin{bmatrix} x_{n|n-1}^{IQ} \\ b_{n}^{IQ} \end{bmatrix}$$

(36)

In order to linearise the nonlinear relation between the state and the measurement equation, the following Jacobian matrix followed from (17) and (30) under the assumption (34) is used:

$$C^{IQ}[x_{n|n-1}^{IQ}, b_{n}^{IQ}] = \begin{bmatrix} C_{\phi}^{IQ} [x_{n|n-1}^{IQ}, b_{n}^{IQ}] \begin{bmatrix} 1 \times 2 \\ 0_{1 \times 2} \end{bmatrix} \\ C_{b}^{IQ} [x_{n|n-1}^{IQ}, b_{n}^{IQ}] \end{bmatrix}$$

(37)

The error covariance matrix of size $2L + 2 \times 2L + 2$ of the a priori estimator error for the EKF is then

$$P_{n|n-1}^{IQ} = A^{IQ} P_{n-1|n-1}^{IQ} (A^{IQ})^T + Q_{-1}^{IQ}$$

(38)

The Kalman gain at time instant $n$ is described by the matrix of size $2L + 2 \times 2$ of the following form

$$G_{n}^{IQ} = P_{n|n-1}^{IQ} C_{\phi}^{IQ} \begin{bmatrix} x_{n|n-1}^{IQ}, b_{n}^{IQ} \end{bmatrix} + R_{-1}^{IQ}$$

(39)

The a priori estimation error of the measurement equation $y_{n|n-1}^{IQ}$ according to the true measure $y_{n}^{IQ}$ is described by the following difference

$$e_{n|n-1}^{IQ} = y_{n}^{IQ} - y_{n|n-1}^{IQ}$$

(40)

Now, the a posteriori estimate of the process equation $\hat{x}_{n|n}^{IQ}$ is the vector of size $2L + 2 \times 1$ of the following form

$$\hat{x}_{n|n}^{IQ} = \hat{x}_{n|n-1}^{IQ} + G_{n}^{IQ} (y_{n}^{IQ} - c^{IQ}[x_{n|n-1}, b_{n}])$$

(41)

The error covariance matrix of size $2L + 2 \times 2L + 2$ of the a posteriori state estimate at time instant $n$ is described by

$$P_{n|n}^{IQ} = \left( I_{2L+2} - G_{n}^{IQ} C_{\phi}^{IQ} \begin{bmatrix} x_{n|n-1}^{IQ}, b_{n}^{IQ} \end{bmatrix} \right) P_{n|n-1}^{IQ}$$

(42)

Thus, all the equations for the joint carrier and channel estimation using the EKF are presented above.

1) Initialization: For the initialization purposes, at time instant $n = 0$ the state noise covariance matrix $Q_{-1}^{IQ}$, the measurement noise covariance matrix $R_{-1}^{IQ}$ and the a posteriori state error covariance matrix $P_{n-1|n-1}^{IQ}$ must be provided.

At first, the state noise covariance matrix $Q_{-1}^{IQ}$ will be defined. We assume, that each element of the state noise process represented by the vector $w_{n}^{IQ}$ of size $2L + 2 \times 1$ is statistically independent random process modelled by the AWGN [3], [9], [10]. Under the above assumption, the state noise covariance matrix is a diagonal matrix of size $2L + 2 \times 2L + 2$ defined as

$$Q_{-1}^{IQ} = E \{ w_{n}^{IQ} w_{n}^{IQ*} \} = \text{diag} \{ \sigma_{w_1}^2, \sigma_{w_2}^2, \sigma_{w_1}^2 \}$$

(43)

where $\sigma_{w_1}^2$ and $\sigma_{w_2}^2$ is an initial phase and frequency variance and $\sigma_{w_1}^2$ is an initial variance of the channel taps defined by...
the vector of size $2L \times 1$ of the following form

$$
\begin{bmatrix}
\sigma^2_{\omega n_0(0)}, \ldots, \sigma^2_{\omega n_0(L-1)} \\
\sigma^2_{\omega n_1(0)}, \ldots, \sigma^2_{\omega n_1(L-1)}
\end{bmatrix}^T
$$

(44)

Under the assumption, that the measurement noise vector $\mathbf{v}_{n}^{Q}$ is AWGN, the measurement noise covariance matrix is defined by a diagonal matrix of size $2 \times 2$ as

$$
R_{-1}^{Q} = E \{ \mathbf{v}_{n}^{Q} \mathbf{v}_{n}^{Q\,T} \} = \text{diag} \{ \sigma^2_v, \sigma^2_v \}
$$

(45)

Following the assumptions presented in [3] and [8] for the channel estimation and the synchronization purposes using the Kalman filtering, we propose to assume the a posteriori state error covariance matrix in the initialization stage to be the diagonal matrix of size $2L + 2 \times 2L + 2$ described as

$$
P_{-1}^{Q} = E \{ \mathbf{w}_{n}^{Q} \mathbf{w}_{n}^{Q\,T} \} = \text{diag} \{ \sigma^2_{\omega_{-1,-1}}, \sigma^2_{\omega_{-1,-1}}, \sigma^2_{\omega_{-1,-1}} \}
$$

(46)

where the channel estimation covariance error $\sigma^2_{\omega_{-1,-1}}$ is defined by the following vector of size $2L \times 1$

$$
\begin{bmatrix}
\sigma^2_{\omega_{n_0,-1,-1}}(0), \ldots, \sigma^2_{\omega_{n_1,-1,-1}}(L-1), \\
\sigma^2_{\omega_{n_2,-1,-1}}(0), \ldots, \sigma^2_{\omega_{n_3,-1,-1}}(L-1)
\end{bmatrix}^T
$$

(47)

IV. ALGORITHM SUMMARY

Proposed algorithm can be presented by the block diagram depicted in Fig. 1. In order to summarize its main stages, it can be divided into the initialization and the Kalman recursion in the following way

- **Initialization:**
  - A posteriori estimate of the process equation ($2L + 2 \times 1$)
    $$
x_{-1|1}^{Q} = \mathbf{0}_{2L+2 \times 1}
$$
    (48)
  - A posteriori state error covariance ($2L + 2 \times 2L + 2$)
    $$
P_{-1|1}^{Q} = \text{diag} \{ \sigma^2_v, \sigma^2_v \}
$$
    (49)
  - Measurement noise covariance ($2 \times 2$)
    $$
    R_{-1}^{Q} = \text{diag} \{ \sigma^2_v, \sigma^2_v \}
    $$
    (50)
  - State noise covariance ($2L + 2 \times 2L + 2$)
    $$
    Q_{-1}^{Q} = \text{diag} \{ \sigma^2_{\omega_{-1,-1}}, \sigma^2_{\omega_{-1,-1}} \}
    $$
    (51)
- **Kalman recursion for $n = 0, 1, 2, \ldots$**
  - Time update step:
    $$
x_{n|n-1}^{Q} = A_{-1}^{Q} x_{n-1|n-1}^{Q}
    $$
    (52)
  - Measurement update step:
    $$
x_{n|n}^{Q} = x_{n|n-1}^{Q} + G_{n}^{Q} \left( y_{n}^{Q} - y_{n}^{Q|n-1} \right)
    $$
    (53)
  - Kalman gain computation:
    $$
    G_{n}^{Q} = P_{n|n-1}^{Q} C_{n|n-1}^{Q} T + Q_{-1}^{Q}
    $$
    (54)

- **Nonlinearity and linearization of the state-space representation:**
  - Nonlinearity between the a posteriori estimate of the state and measure: $y_{n}^{Q|n-1} = c_{-1}^{Q} \left[ x_{n|n-1}, b_{n}^{Q} \right]$
  - Jacobian: $C_{n|n-1}^{Q} = C_{n|n-1}^{Q} \left[ x_{n|n-1}, b_{n}^{Q} \right]$

V. SIMULATION RESULTS

The proposed algorithm for joint channel and carrier estimation, further referenced as the Joint Extended Kalman Filter (JEKF) is compared with the separate Kalman channel estimator [3] concatenated with the extended Kalman carrier recovery [9], which is referenced as the Separate Extended Kalman Filter (SEKF).

The communication channel of length $L$ is assumed to be a single frame time invariant, generated from an uncorrelated and zero mean stationary random process with Gaussian distribution. The channel impulse response has normalized energy, which is $\sum_{l=0}^{L-1} |h_l|^2 = 1$ Additionally, the AWGN is present in the received signal with signal to noise ratio $SNR = 80dB$, except the simulation, in which a relation between the MSE and the SNR is estimated.

In order to calculate the mean square error of the a posteriori estimate of the measurement equation is defined as

$$
y_{n|n} = \mathbf{h}_{n|n}^{T} \mathbf{b}_{n} \exp \{ j \phi_{n|n} \}
$$

(57)

Estimation of the MSE is performed using the Monte Carlo (MC) simulations based on $M = 1000$ runs, and the estimate is calculated as

$$
\text{MSE} \left( n \right) = \frac{1}{M} \sum_{m=0}^{M-1} |c_{n|n}^{(m)}|^2 = \frac{1}{M} \sum_{n=0}^{M-1} |y_{n} - y_{n|n}^{(m)}|^2
$$

(58)

where the upper index $(m)$ represents the number of the MC run.

At first, simulations were focused on the initialization behaviour of the algorithms for different values of the initialization parameters $R_{-1}^{Q}, Q_{-1}^{Q}, P_{-1|1}^{Q}$ and its influence to the speed of adaptation and the steady state mean square error of the a posteriori estimate of the measurement $y_{n|n}$ for both the JEEKF and the SEKF with the same initialization parameters. The channel length is assumed to be $L = 8$ and the residual carrier frequency offset $f_0 = \omega_0/2\pi$ normalized to the symbol frequency $f_s$ is equal to $f_0/f_s = 0.01$.

In Figure 2(a) an influence of the state noise covariance matrix parameter is investigated for initial values $Q_{-1}^{Q} = \left\{ 10^{-2} I, 10^{-3} I, 10^{-4} I \right\}$ with the fixed measurement noise covariance $R_{-1}^{Q} = 0.25 I$ and the a posteriori state error covariance $P_{-1|1}^{Q} = 10^{-3} I$. When the state noise covariance matrix is $Q_{-1}^{Q} = 10^{-2} I$, the JEEKF reaches better results compared with the SEKF in both the speed of
adaptation and the steady state MSE. However, when the measurement noise covariance matrix is $Q_{-1}^{IQ} = \{10^{-3}I, 10^{-7}I\}$, both algorithms behaves in a similar way.

In Figure 2(b) an influence of the measurement error covariance matrix $P_{-1}^{IQ}$ is checked for the speed of adaptation and the steady state MSE is investigated. For simulation purposes, the measurement noise covariance matrix is assumed $R_{-1}^{IQ} = 0.025I$ and the state noise covariance matrix is $Q_{-1}^{IQ} = 10^{-2}I$. According to [3], this parameter in the Kalman channel estimator determines the speed of adaptation, however, for the assumed range of the parameter $P_{-1}^{IQ} = \{10^{-1}I, 10^{-2}I, 10^{-3}I\}$ the speed of adaptation does not change significantly and the steady state MSE estimates remains at the similar level.

In Figure 3(a) an influence of the measurement noise covariance matrix $R_{-1}^{IQ}$ is investigated consecutively for $Q_{-1}^{IQ} = 10^{-2}I$, $P_{-1}^{IQ} = 10^{-3}I$ and $Q_{-1}^{IQ} = 10^{-2}$, $P_{-1}^{IQ} = 10^{-3}I$. For the simulation purposes, the measurement noise covariance $R_{-1}^{IQ} = \{0.25I, 0.025I, 0.0025I\}$. For the JEKF, decreasing the initial value of the measurement noise covariance improved both the speed of adaptation and the steady state mean square error. However, for the SEKF and the same initial parameters, the speed of adaptation and the steady state mean square error is increasing for decreasing the initial value of measurement noise covariance matrix $R_{-1}^{IQ}$.

For further experiments, the initialization parameters are chosen from the results depicted in Figs. 2(a), 2(b) and 3(a) for the best performance of the algorithms. Both of the JEKF configurations have the same a posteriori estimation error covariance matrix $P_{-1}^{IQ}$ and measurement noise covariance matrix $R_{-1}^{IQ} = 0.0025I$, but the state noise covariance for the JEKF I is $Q_{-1}^{IQ} = 10^{-2}I$, and for the JEKF II is $Q_{-1}^{IQ} = 10^{-3}I$. In case of the SEKF, the state
The steady state MSE of the SEKF is degrading when the channel length and the dimension of the vector $\mathbf{x}_n^I$ increase. On the other hand, the steady state MSE of the JEKF I and the JEKF II perform better than the SEKF. However, the JEKF I performs better than the SEKF for the same channel length. Additionally, it can be noted that the steady state MSE for both the JEKF I and the SEKF decreases for about 2.5dB at each step.

VI. CONCLUSION

In this paper the joint channel and carrier estimation technique based on the EKF is proposed. The algorithm is compared with concatenated the KF channel [3] and the EKF carrier estimator [9] in which the state–space models are modified in order to incorporate both types of distortions. For both algorithms the Monte Carlo simulations were performed in order to compare the speed of adaptation and the steady state MSE. The joint channel and carrier estimation using the extended Kalman filter can provide better results than the SEKF and it seems to be an interesting topic for further studies.
